

CPSC 250 - Functions (Methods)

def my-function (.....):

name argument list

↑

return
return value list

argument list: a list of things that are passed to the function.

return value list: a list of things returned from the function.

Example 1:

def add (a , b) :

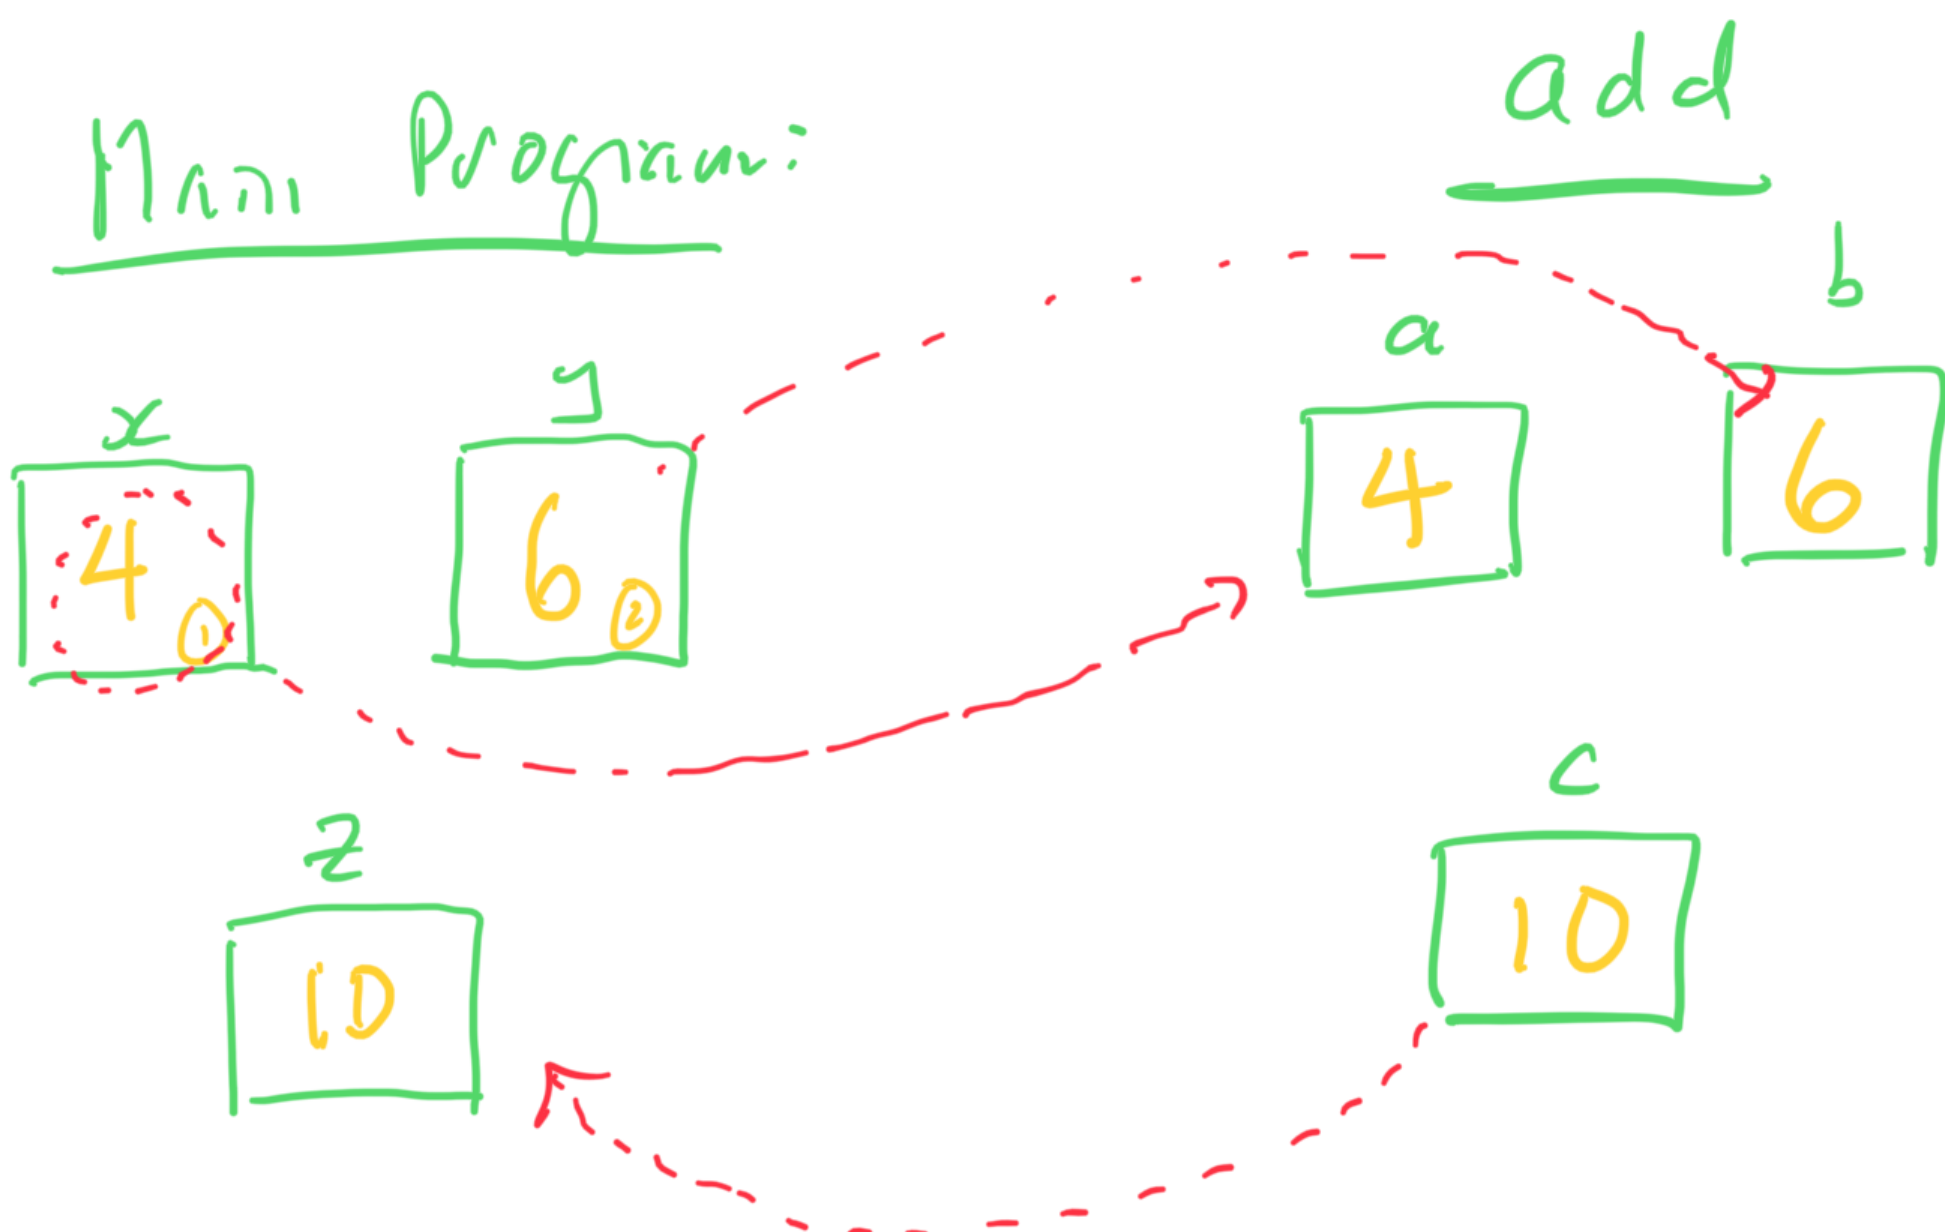

c = a + b

return c

- ① x = 4
- ② y = 6
- ③ z = add(x, y)

Main Program:

Super incredibly important ideas:

① a, b are copies of x, y !!!!!!! They are different places in memory !!

② changing a, b in the function does not change x, y in the main program !!

This is called PASS BY VALUE !!

Big Hint: Use different variable names in the main program and the function !!

Main

x, y, z

Function

a, b, c

This will reinforce to the reader, and to you, that the variables in the function are different than in the

main program ☺.

static typing (C, C++, Java, Go, ...)

A note on dynamic typing (or duck typing) in Python:

The add function above would work equally well on strings or floats!!

Python is smart enough to make a, b, and c whatever type they need to be!

```
x = "that is"
```

```
y = "so cool!"
```

```
z = add(x, y)
```

```
print(z)
```

Scope:

where, where the
do variables have a
well defined meaning.

Ex.

employee_name = 'Bob'

def get_name():

① name = input()

employee_name = name

→ get_name()

print(employee_name)

Pass by Reference

main

change_numbers
